

Features

- Very high speed
 - 55 ns
- Wide voltage range
 - 2.2 V to 3.7 V
- Ultra low standby power
 - Typical standby current: 8 μ A
 - Maximum standby current: 48 μ A
- Ultra low active power
 - Typical active current: 7.5 mA at f = 1 MHz
- Easy memory expansion with $\overline{CE}_1$, CE_2 , and $\overline{OE}$ features
- Automatic power down when deselected
- CMOS for optimum speed and power
- Available in Pb-free 48-ball FBGA package

Functional Description

The CY62187EV30 is a high performance CMOS static RAM organized as 4 M words by 16-bits. This device features advanced circuit design to provide ultra low active current. It is ideal for providing More Battery Life™ (MoBL®) in portable applications such as cellular telephones. The device also has an automatic power down feature that significantly reduces power consumption by 99 percent when addresses are not toggling. The device can also be put into standby mode when deselected ($\overline{CE}_1$ HIGH or CE_2 LOW or both $\overline{BHE}$ and $\overline{BLE}$ are HIGH). The input and output pins (I/O_0 through I/O_{15}) are placed in a high impedance state when deselected ($\overline{CE}_1$ HIGH or CE_2 LOW), outputs are disabled ($\overline{OE}$ HIGH), both Byte High Enable and Byte Low Enable are disabled ($\overline{BHE}$, $\overline{BLE}$ HIGH), or during a write operation ($\overline{CE}_1$ LOW, CE_2 HIGH and $\overline{WE}$ LOW).

To write to the device, take Chip Enables ($\overline{CE}_1$ LOW and CE_2 HIGH) and Write Enable ($\overline{WE}$) input LOW. If Byte Low Enable ($\overline{BLE}$) is LOW, then data from I/O pins (I/O_0 through I/O_7), is written into the location specified on the address pins (A_0 through A_{21}). If Byte High Enable ($\overline{BHE}$) is LOW, then data from I/O pins (I/O_8 through I/O_{15}) is written into the location specified on the address pins (A_0 through A_{21}).

To read from the device, take Chip Enables ($\overline{CE}_1$ LOW and CE_2 HIGH) and Output Enable ($\overline{OE}$) LOW while forcing the Write Enable ($\overline{WE}$) HIGH. If Byte Low Enable ($\overline{BLE}$) is LOW, then data from the memory location specified by the address pins appear on I/O_0 to I/O_7 . If Byte High Enable ($\overline{BHE}$) is LOW, then data from memory appears on I/O_8 to I/O_{15} . See the [Truth Table](#) on page 9 for a complete description of read and write modes.

Notes

2. $V_{IL(min)}$ = -2.0V for pulse durations less than 20 ns.

3. $V_{IH(max)}$ = $V_{CC} + 0.75\text{ V}$ for pulse durations less than 20 ns.

4. Full Device AC operation assumes a 100 μs ramp time from 0 to $V_{CC(min)}$ and 200 μs wait time after V_{CC} stabilization.

5. Typical values are included for reference only and are not guaranteed or tested. Typical values are measured at $V_{CC} = V_{CC(typ)}$, $T_A = 25\text{ °C}$.

6. Under DC conditions the device meets a V_{IL} of 0.8 V. However, in dynamic conditions input LOW Voltage applied to the device must not be higher than 0.7 V.

7. Chip enables ($\overline{CE}_1$ and CE_2), Address Pins A_{20} , A_{21} and Byte Enables (BHE and BLE) need to be tied to CMOS levels to meet the I_{SB2} / I_{CCDR} spec. Other inputs can be left floating.

Notes

9. Typical values are included for reference only and are not guaranteed or tested. Typical values are measured at $V_{CC} = V_{CC(typ)}$, $T_A = 25$ °C.
10. Chip enables ($\overline{CE}_1$ and CE_2), Address Pins A_{20} , A_{21} and Byte Enables ($\overline{BHE}$ and $\overline{BLE}$) need to be tied to CMOS levels to meet the I_{SB2}/I_{CCDR} spec. Other inputs can be left floating.
11. Tested initially and after any design or process changes that may affect these parameters.
12. Full device operation requires linear V_{CC} ramp from V_{DR} to $V_{CC(min)} \geq 100$ μ s or stable at $V_{CC(min)} \geq 100$ μ s.
13. $\overline{BHE.BLE}$ is the AND of both $\overline{BHE}$ and $\overline{BLE}$. Chip is deselected by either disabling the chip enable signals or by disabling both $\overline{BHE}$ and $\overline{BLE}$.

Notes

14. In an earlier revision of this device, under a specific application condition, READ and WRITE operations were limited to switching of the byte enable and/or chip enable signals as described in the Application Note AN66311. However, the issue has been fixed and in production now, and hence, this Application Note is no longer applicable. It is available for download on our website as it contains information on the date code of the parts, beyond which the fix has been in production.
15. Test conditions for all parameters other than tri-state parameters assume signal transition time of 1 V/ns, timing reference levels of V_{TH} , input pulse levels of 0 to $V_{CC(typ)}$, and output loading of the specified I_{OL}/I_{OH} as shown in Figure 2 on page 6.
16. At any temperature and voltage condition, t_{HZCE} is less than t_{LZCE} , t_{HZBE} is less than t_{LZBE} , t_{HZOE} is less than t_{LZOE} , and t_{HZWE} is less than t_{LZWE} for any given device.
17. t_{HZOE} , t_{HZCE} , t_{HZBE} , and t_{HZWE} transitions are measured when the outputs enter a high impedance state.
18. The internal Write time of the memory is defined by the overlap of $\overline{WE}$, $CE_1 = V_{IL}$, BHE and/or BLE = V_{IL} , and $CE_2 = V_{IH}$. All signals must be ACTIVE to initiate a write and any of these signals can terminate a write by going INACTIVE. The data input setup and hold timing should be referenced to the edge of the signal that terminates the write.
19. The minimum write cycle pulse width for Write Cycle No. 3 ($\overline{WE}$ controlled, $\overline{OE}$ LOW) should be equal to the sum of t_{SD} and t_{HZWE} .

Figure 4. Read Cycle 1 (Address Transition Controlled) [20, 21]

20. The device is continuously selected. $\overline{\text{OE}}$, $\overline{\text{CE}}_1 = V_{\text{IL}}$, $\overline{\text{BHE}}$ and/or $\overline{\text{BLE}} = V_{\text{IL}}$, and $\text{CE}_2 = V_{\text{IH}}$.
 21. $\overline{\text{WE}}$ is HIGH for read cycle.
 22. Address valid prior to or coincident with $\overline{\text{CE}}_1$, $\overline{\text{BHE}}$, $\overline{\text{BLE}}$ transition LOW and CE_2 transition HIGH.

Switching Waveforms (continued)

Figure 6. Write Cycle 1 ($\overline{WE}$ Controlled) [23, 24, 25, 26]

Figure 7. Write Cycle 2 ($\overline{CE}_1$ or CE_2 Controlled) [23, 24, 25, 26]

Notes

23. The internal Write time of the memory is defined by the overlap of $\overline{WE}$, $\overline{CE}_1 = V_{IL}$, $\overline{BHE}$ and/or $\overline{BLE} = V_{IL}$, and $CE_2 = V_{IH}$. All signals must be ACTIVE to initiate a write and any of these signals can terminate a write by going INACTIVE. The data input setup and hold timing should be referenced to the edge of the signal that terminates the write.

24. Data I/O is high impedance if $\overline{OE} = V_{IH}$.

25. If $\overline{CE}_1$ goes HIGH and CE_2 goes LOW simultaneously with $\overline{WE} = V_{IH}$, the output remains in a high impedance state.

26. During this period the I/Os are in output state and input signals should not be applied.

Switching Waveforms (continued)

Figure 9. Write Cycle 4 ($\overline{\text{BHE/BLE}}$ Controlled, $\overline{\text{OE}}$ LOW) [27, 28]

Notes

27. If $\overline{\text{CE}}_1$ goes HIGH and CE_2 goes LOW simultaneously with $\overline{\text{WE}} = V_{IH}$, the output remains in a high impedance state.

28. During this period the I/Os are in output state and input signals should not be applied.

29. The minimum write cycle pulse width should be equal to the sum of t_{SD} and t_{HZWE} .
