

USB charging controller with integrated power switch and attach detector

Datasheet - production data

Features

- Compliant with USB charging specifications BC1.2, USB 2.0 and USB 3.0 standards
- Compliant with Chinese telecommunications industry standard YD/T 1591-2009
- Compatible with proprietary charging mode (Apple® 1 A / 2 A, BlackBerry®, Korean tablets)
- Wide bandwidth, low-loss USB 2.0 data switch
- Integrated V_{BUS} power switch with low R_{ON} of 65 m Ω
- Constant current mode overcurrent protection
- Soft-start to limit inrush current
- Adjustable current limit up to 2.8 A
- Short-circuit, thermal and undervoltage protection
- Reverse voltage and reverse current protection
- Deglitched fault reporting output
- Supports remote wakeup in S3
- Charging indication output in DCP and CDP modes
- 3-hour safety counter for charging in S5
- Device attachment detection in G3 state
- Available in VFQFPN 16L
3 x 3 x 0.8 mm package with exposed pad
- Temperature range: -40 up to 85 °C
- UL and CB recognized components
(UL file number: E354278)

Applications

- USB ports/hubs
- Personal computers, all-in-one PCs
- Monitors
- Notebooks, ultrabooks
- Tablet PCs
- Universal wall charging adapters

Description

The STCC5011/STCC5021 device integrates, in one package, a USB charger controller, a wide bandwidth data switch and a high current power switch. The device emulates several profiles compatible with the USB battery charging standard BC1.2, Chinese telecommunications standard YD/T 1591-2009 and proprietary charger modes.

The device can detect peripheral device attachment when the host is in a G3 state. It asserts the CHARGING/ATTACH output after the attach event, allowing the host to turn on the high power DC-DC converter and start charging.

This device also asserts the CHARGING/ATTACH output in DCP modes if the charging current is above the threshold. In CDP mode, it asserts the CHARGING/ATTACH output after the CDP negotiation if the charging current is above the threshold.

After the current drops below the threshold, the output is deasserted. This allows the host to turn off the high power DC-DC converter and reduce overall consumption in S4/S5 states which is critical when the host is battery-supplied.

These two features permit the host system to reduce consumption while no device is attached or when there is no charging.

1 Functional description

The STCC5011 and STCC5021 devices integrate, in one package, a complete solution to charge portable devices through USB ports. Functions include:

- Charger emulator compatible with USB battery charging BC1.2 standard, Chinese telecommunications standard YD/T 1591-2009 and proprietary chargers such as Apple® divider mode, BlackBerry® and Korean tablet charging mode.
- The Apple divider mode comes in 2 profiles:
 - 1 A max. current drawn: for Apple iPod®, iPhone® (STCC5011)
 - 2 A max. current drawn: for Apple iPad®, supporting also Apple iPod and iPhone (STCC5021)
- 3 control pins, CTL1, CTL2, CTL3 allowing the host to select the emulation profile. These pins may be controlled directly from the host USB controller or from the embedded controller.
- USB data switch with wide bandwidth up to 1100 MHz compliant with USB 2.0 standard. This wide bandwidth switch features low capacitance and low R_{ON} resistance, allowing signals to pass with minimum edge and phase distortion.
- N-channel power switch with low R_{ON} resistance of 65 mΩ typ., high current limiter accuracy and high current output capability, 2.5 A typ. The current limit threshold can be adjusted with a good accuracy by an external resistor in the range 500 mA to 2.8 A. Constant current mode protection is used to protect the device and the host system against overcurrent or short-circuit. Other protection includes reverse current and reverse voltage protection, undervoltage lockout and thermal shutdown.
- A deglitched output (\overline{FAULT}) reporting the failure events of overcurrent, thermal shutdown and reverse current (backdrive) to V_{IN} .
- Charging current sensing circuit. The output $\overline{CHARGING/ATTACH}$ is asserted if charging current is above 20 mA in CDP and DCP modes.
In CDP mode the charging flag is asserted only if the CDP handshaking between the portable device and the host is performed before the current is above the threshold. Moreover, in S4/S5 power states and battery supplied, there is an additional safety timer to stop the charging process when the “end of charge” timeout is reached. This timer is started only after a device attachment event and can be disabled by toggling the pin ATTACH_EN to low if the timer is not wanted.
 If the timeout or current is below the threshold, the signal $\overline{CHARGING/ATTACH}$ is deasserted: in both cases, the host system can disable the high power DC-DC converter and therefore reduce power consumption. This is crucial when the host is battery supplied.
- Attach detector circuit to monitor device attachment.
 This circuit is enabled by driving the ATTACH_EN pin high and EN low. When a device attachment is detected, the output $\overline{CHARGING/ATTACH}$ is asserted for a t_{ATTACH} period (25 s typ.). The attach detection block is supplied by the V_{DD} power supply pin.
- An enable input (EN) to enable/disable the device, except the attach detection switch which is also managed by the ATTACH_EN input.

The device is offered in a small, RoHS-compliant VFQFPN 16L (3 x 3 x 0.8 mm) package with an exposed pad for effective cooling.

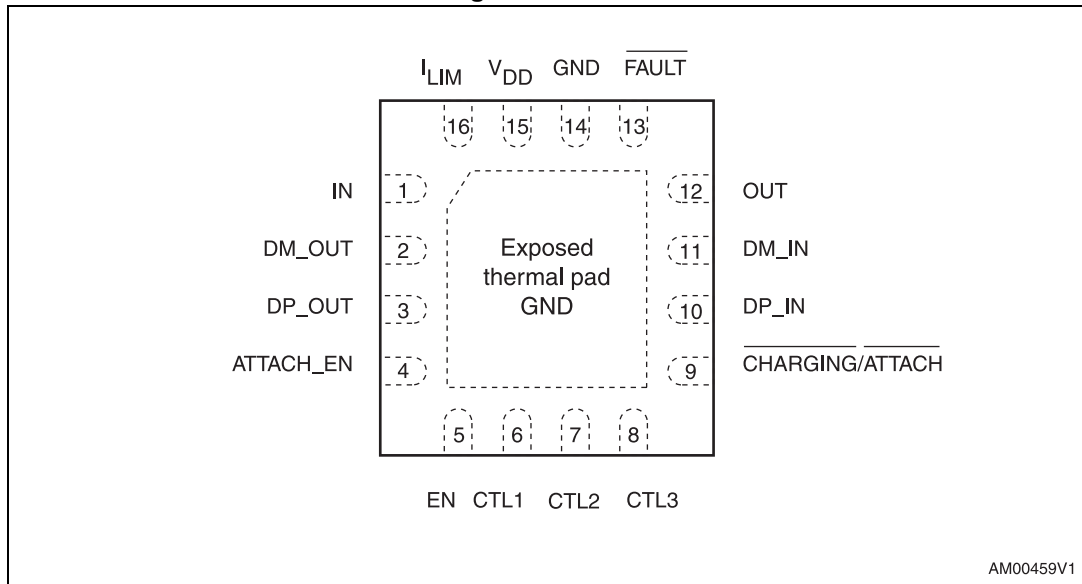

Figure 2. Pinout

2 Pin description

Table 1. Pin description

Pin no.	Name	Type	Description
1	IN	PWR	Device and USB port power supply input
2, 3	DM_OUT, DP_OUT	I/O	USB 2.0 data connection to system USB transmitter (DM = D-, DP = D+)
4	ATTACH_EN	I	Logic level control input to turn on/off the attach detector (see Table 6). It can also disable (logic low) the 3-hour timer if started.
5	EN	I	Logic level control input. When EN is low, power switch, data switch and emulator are OFF.
6, 7, 8	CTL1, CTL2, CTL3	I	Logic level control inputs to select charger mode (see Table 5).
9	$\overline{\text{CHARGING/ATTACH}}$	O	Active low open drain output, asserted when device attachment or charging current is detected.
10, 11	DP_IN, DM_IN	I/O	USB 2.0 data connection to system USB connector (DM = D-, DP = D+)
12	OUT	PWR	USB port power supply output (V_{BUS})
13	$\overline{\text{FAULT}}$	O	Active low open drain output, asserted when overcurrent, overtemperature or reverse voltage are detected.
14	GND	-	Ground
15	V_{DD}	PWR	Attach detector power supply. V_{DD} must always be supplied before V_{IN} .
16	I_{LIM}	I	Current limit threshold programming resistor terminal

3 Absolute maximum ratings and operating conditions

Stressing the device beyond the rating listed in [Table 2: Absolute maximum ratings \(AMR\)](#) may cause permanent damage to the device. These are stress ratings only and functional operation of the device at these or any other conditions beyond those indicated in [Table 3: Operating conditions](#) is not implied. Exposure to absolute maximum rating conditions for extended periods may affect device reliability.

Table 2. Absolute maximum ratings (AMR)

Symbol	Parameter	Value	Unit
V_{IN}, V_{DD}, V_{OUT}	Supply voltage	-0.3 to 6.5	V
$V_{EN}, V_{ATTACH_EN}, V_{CTLX}$	Logical input voltage		
$\frac{V_{FAULT}, V_{CHARGING/ATTACH}}$	Pull-up resistor voltage ($\overline{FAULT}, \overline{CHARGING/ATTACH}$)		
$V_{DP_OUT}, V_{DM_OUT}, V_{DP_IN}, V_{DM_IN}$	Data switch pin voltage to ground	-0.3 to $V_{IN} + 0.3$	V
$I_{DP_OUT}, I_{DM_OUT}, I_{DP_IN}, I_{DM_IN}$	Data switch current, switch ON	±50	mA
$I_{O(OUT)}$	Maximum power switch output current, power switch ON	Internally limited	A
$\frac{I_{O(FAULT)}, I_{O(CHARGING/ATTACH)}}$	Logical output sink current	25	mA
T_{STG}	Storage temperature (V_{IN} OFF, V_{DD} OFF)	-55 to +150	°C
T_{SLD}	Lead solder temperature for 10 second temperature (V_{IN} OFF, V_{DD} OFF) ⁽¹⁾	260	
R_{thja}	Thermal resistance junction-to-ambient VFQFPN 16L ⁽²⁾	60	°C/W
T_j	Maximum junction temperature range (internally limited)	-40 to T_{STOP}	°C
$V_{ESD(OUT, DP_IN, DM_IN)}$	IEC61000-4-2 contact discharge (OUT, DP_IN, DM_IN pins) ⁽³⁾	8	kV
V_{ESD}	JEDEC human body model (all pins)	2	
	JEDEC machine model (all pins)	200	V

1. Reflow at temperatures of 255 °C to 260 °C for time < 30 seconds (total thermal budget not to exceed 180 °C for a period from 90 to 150 seconds).
2. R_{th} are typical values, given when mounted on a 4-layer PCB with vias.
3. Measured in a recommended application circuit with a 1 μF ceramic capacitor + 150 μF low ESR electrolytic capacitor connected between OUT and GND pins (see [Figure 4](#)).

Table 3. Operating conditions

Symbol	Parameter	Value	Unit
V_{IN}	Supply voltage	4.5 to 5.5	V
V_{DD}	Supply voltage	1.7 to 5.5	
T_A	Ambient operating temperature	-40 to +85	°C
T_J	Junction operating temperature	-40 to +125	

4 Electrical characteristics

Table 4. Electrical characteristics $V_{IN} = 4.5\text{ V to }5.5\text{ V}$, $V_{DD} = 1.7\text{ V to }5.5\text{ V}$, $-40\text{ }^\circ\text{C} < T_J < 125\text{ }^\circ\text{C}$ (unless otherwise specified)

Symbol	Parameter	Conditions	Min.	Typ.	Max.	Unit
Current consumption (V_{IN} domain)						
$I_{IN(ACTIVE)}$	Supply current in active state (EN = 1)	Mode CDP (111)		110	160	μA

Figure 3. Timing waveforms

AM00461V1

5.1 Supported modes

For more information refer to [Section 5.4: State machine](#).

The STCC5011/STCC5021 device supports the following modes:

- SDP BC1.2
- CDP BC1.2
- SDP with remote wakeup for all USB devices
- CDP with remote wakeup for low-speed USB devices with automatic transition to DCP auto-mode if a full-speed/high-speed USB device attached or after a USB device detached
- DCP auto-detect: this mode permits auto-detection of charging modes between DCP BC1.2 (shorted D+, D-) and divider charging mode. It also supports BlackBerry charging mode and can charge legacy devices and Korean tablets.
- Forced DCP BC1.2 mode
- Forced DCP divider mode

The auto-detect mode starts in divider mode. If a charging negotiation attempt is detected, there is an automatic transition to DCP BC1.2 mode. It is preceded by a V_{BUS} discharge pulse to initialize the proper BC1.2 handshake process. If the BC1.2 device is detached, the circuit automatically returns to divider mode after a 10 s (typ.) timeout.

Note: From the application point of view it means that after removing one device the user should wait for approx. 15 s before attaching another device.

Selection between these modes is made through the CTLx control pins. The CTLx pins may be controlled by the host in different ways:

- GPIO from the embedded controller
- Hardware signals from the USB host controller (SLP_S3#, SLP_S4#) and the AC_adapter signal from the embedded controller
- Hardware signal SUSPEND from the embedded controller and AC_ADAPTER.

Table 5. Truth table control pins CTLx⁽¹⁾

Host state	CTL1	CTL2	CTL3	Mode description
	0	0	0	Device off, output discharge
S0, S1 (S3) ⁽²⁾	1	1	0	SDP
S0, S1, (S3) ⁽²⁾	1	1	1	CDP BC1.2 with charging detection.
S3, (S0, S1) ⁽²⁾	0	1	0	SDP with remote wakeup for all USB devices
S3	0	1	1	CDP with remote wakeup for low-speed USB devices / DCP auto-mode for full-speed or high-speed USB devices or after a USB device detached.
S4, S5	0	0	1	DCP auto-detect mode without remote wakeup, with charging detection
S4, S5	1	0	1	Forced DCP divider mode with charging detection
S4, S5	1	0	0	Forced DCP BC1.2 mode with charging detection

1. On the transition from the CTLx = 111 to CTLx = 001, a synchronous transition of the CTL1 and CTL2 must be ensured.
2. See [Section 5.2](#) for further information.

5.2 Remote wakeup in S3

For more information refer to [Section 5.4: State machine](#).

If the CTLx pins are controlled by hardware signals (such as SLP_Sx# or SUSPEND), the CTLx combination changes when the host transitions from S0 to S3 and back. In this case, the STCC5011/STCC5021 device can support remote wakeup of portable devices for the following transitions (i.e. no V_{BUS} discharge pulse and data switch ON):

- SDP S0 (CTLx = 110) to and from SDP S3 (CTLx = 010) for all USB devices
- SDP (CTLx = x10) and CDP S0 (CTLx = 111) to and from CDP S3 (CLx = 011) for low-speed USB devices only.

If the host system is in S3 mode (CTLx = 011), the system automatically turns into DCP auto-mode for already attached full-speed / high-speed USB devices or after any USB device is detached. Thus, already attached full-speed / high-speed devices or newly attached devices are charged without the need of CTLx transition.

If the S0 to S3 transition is managed by GPIO from the embedded controller, the easiest solution is to keep the same levels on the CTLx pins (SDP or CDP modes). Therefore, remote wakeup in S3 is supported for all USB devices but the system does not automatically turn into DCP auto-mode.

5.3 V_{BUS} discharge

The V_{BUS} discharge pulse lasts for 350 ms typ. ($t_{V_{BUS_REAPP}}$) and is performed for any transitions between the modes listed in [Table 5](#), except the modes allowing remote wakeup in S3 [transitions (x10) and (111) to/from (011)].

Permanent output discharge is provided in the following modes:

- EN = 0, ATTACH_EN = 0, CTLx = xxx (ignored)
- EN = 1, ATTACH_EN = 0, CTLx = 000.

5.4 State machine

Figure 5. State machine

5.5 Attach detection

The STCC5011-STCC5021 can detect device attachment when the host system is in the G3 state. The combination of logic low level on EN and logic high on ATTACH_EN enables a bypass switch, supplied by low power supply, V_{DD} (see [Table 6](#)). It allows the host to keep only low power supply LDO alive, therefore reducing its power consumption in G3 state while there is no device attached, but maintaining the possibility to wakeup. It also prevents “no charging” attached devices (“power thieves”) to draw current.

Table 6. Attach detector truth table

ATTACH_EN	EN	Attach detector
0	x	OFF
1	1	OFF
1	0	ON

The attach detection circuit has a very low consumption (12 μ A typ.) and accepts a wide supply voltage range (1.7 V up to 5.5 V).

The devices already attached before entering the G3 state (EN = 0, ATTACH_EN = 1) are ignored and their current consumption is limited to 500 μ A. Only devices attached after entering the G3 state are detected.

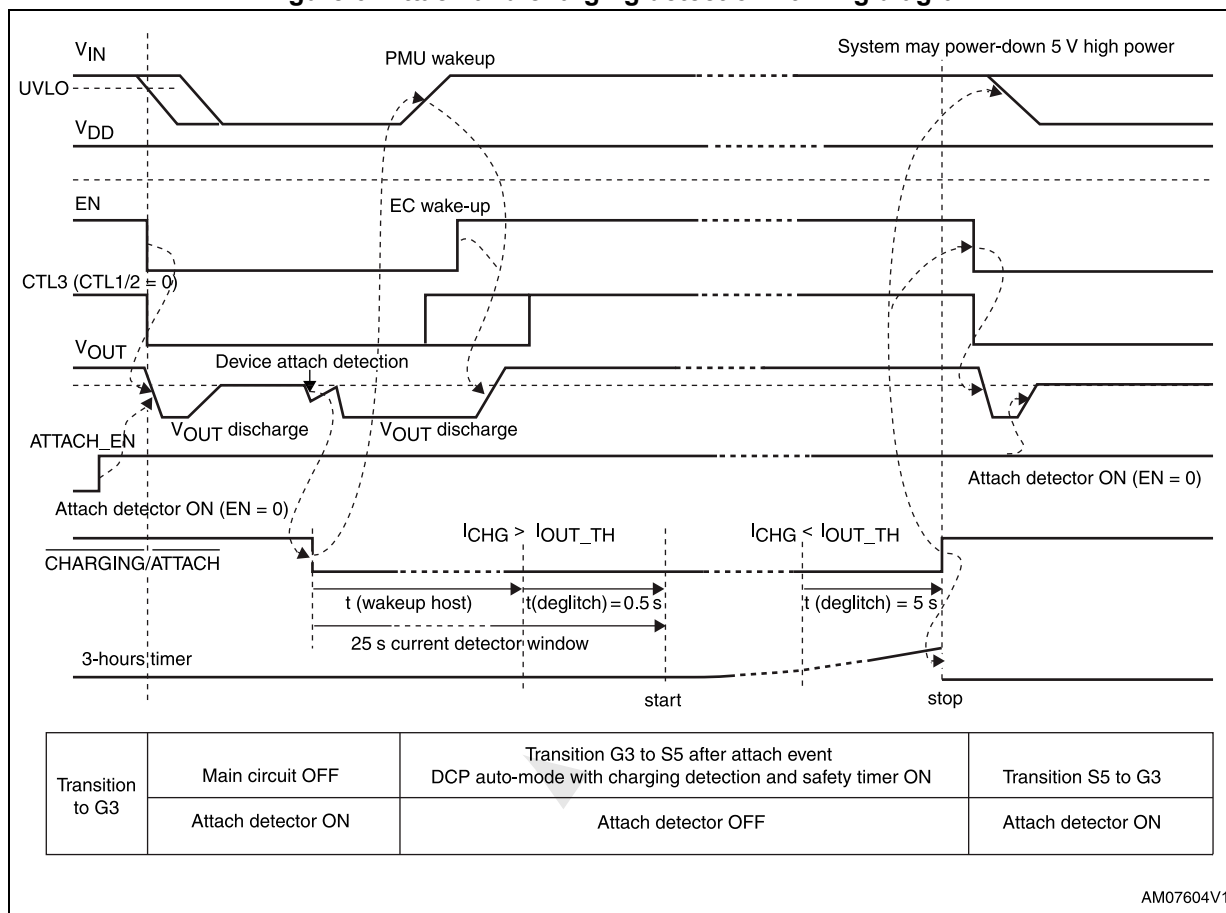

The attach detector monitors voltage drop across the bypass switch between V_{DD} and V_{OUT} . This voltage drop is caused either by the supply current of the attached device or by inrush current for charging device internal capacitors.

An open drain active low output $\overline{\text{CHARGING/ATTACH}}$ is asserted upon device detection, alerting the host system of device attachment. It stays asserted for the t_{ATTACH} delay (25 s typically). During this time the host may switch from G3 state to S5 state, start high power 5 V supply for V_{IN} and set proper CTLx configuration (see [Figure 6](#)).

The attached device can start charging keeping $\overline{\text{CHARGING/ATTACH}}$ asserted.

If charging does not occur, the flag is deasserted after the t_{ATTACH} (the attached device removed or charging current drops below threshold or safety timer expires - see [Section 5.6](#)).

Figure 6. Attach and charging detection - timing diagram

5.6 Charging detection and safety timer

The STCC5011-STCC5021 devices continuously monitor current drawn by the portable device. While programmed in CDP or DCP mode, the STCC5011-STCC5021 devices send a charging flag to the system if the current through the USB power switch is above the charging threshold, set at 20 mA typ.: open drain active low output CHARGING/ATTACH is asserted.

Note: In CDP mode the charging flag is asserted only if the CDP handshaking between the portable device and the host is performed before the current is above threshold.

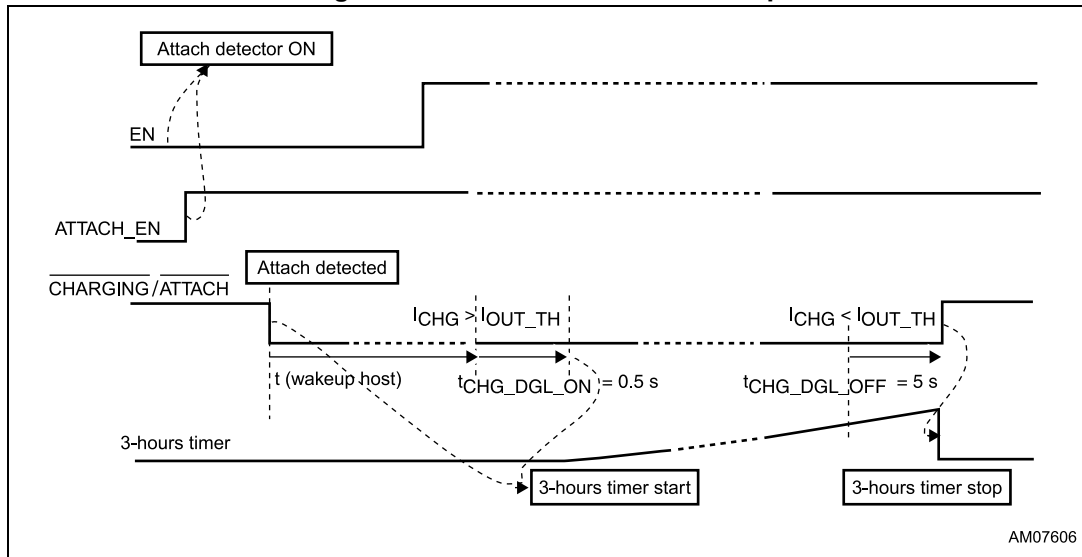

If the CHARGING/ATTACH output is already asserted because of attachment detection (while the host is in G3 state), this output stays unchanged.

For systems in S5 providing current charge while being battery supplied, there is a safety timer integrated into the STCC5011-STCC5021 devices. This timer is started only after an attach event with input ATTACH_EN enabled.

The safety timer is stopped in the following conditions:

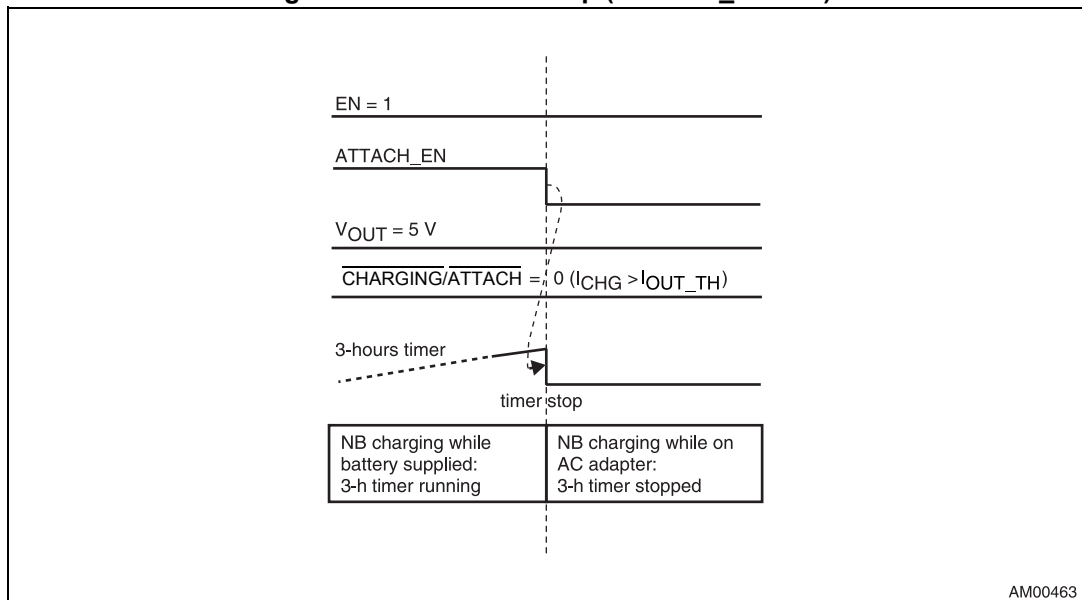

- Charging current below threshold (see [Figure 7](#)). The $\overline{\text{CHARGING/ATTACH}}$ output is deasserted.
- End of 3 hours (timer expires). The $\overline{\text{CHARGING/ATTACH}}$ output is deasserted.
- ATTACH_EN transition to 0 (see [Figure 8](#)). The $\overline{\text{CHARGING/ATTACH}}$ output is intact and the charging can continue without any time limit.

Figure 7. 3-hour timer - start and stop

AM07606

Figure 8. 3-hour timer stop (ATTACH_EN low)

AM00463

Use case 1: device charging in CDP, notebook is then turned off

If a device is charging while the system is turned off and the battery supplied, the risk is that the charging process stops before the end of charge due to the system power-off. To avoid this, the flag CHARGING/ATTACH can be used by the host to prevent the switching-off of the high power DC-DC converter when the host goes to S5 state, even if battery supplied. In this case the 3-h timer is not started.

Use case 2: charging in S5, battery supplied

Once device attachment has been detected and the host has woken up, supplying V_{BUS} voltage to the portable device allows the charging process to start in DCP mode. The flag CHARGING/ATTACH stays asserted for the t_{ATTACH} period (25 s typ.) after attach. During this period, the charging must be established (charging current above the I_{OUT_TH} threshold) to keep the CHARGING/ATTACH output asserted. The 3-h safety timer is started if ATTACH_EN is kept high.

If, for whatever reason, there is no charging current (or if it is below 20 mA), CHARGING/ATTACH is deasserted (while ATTACH_EN is still high). The host can return to its previous state by switching off the high power supply, to reduce consumption, and setting the EN pin to 0. Therefore, the attach detector is ON. At this stage, the STCC5011-STCC5021 devices can detect if the device is still attached or has been removed (see Figure 9).

- If the device is still attached, the attach detector circuit waits for device removal.
- If the device is removed, the circuit goes back into attach detection mode till the next attachment.

Figure 9. Attach detection

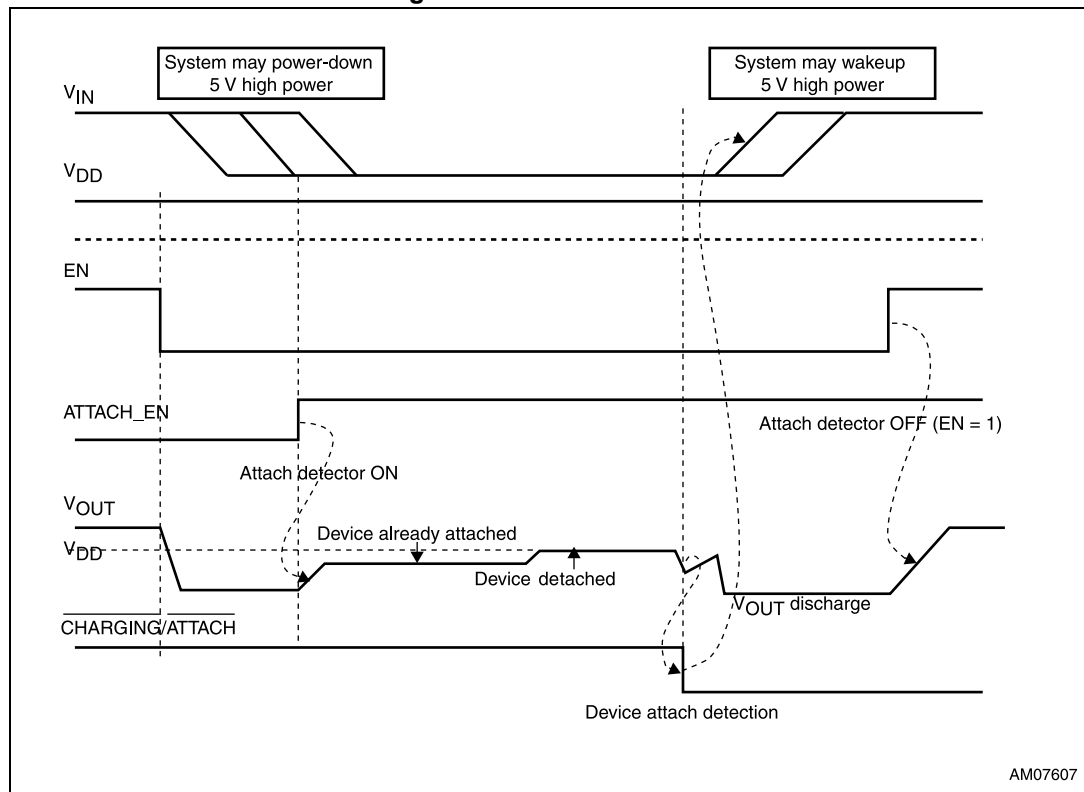

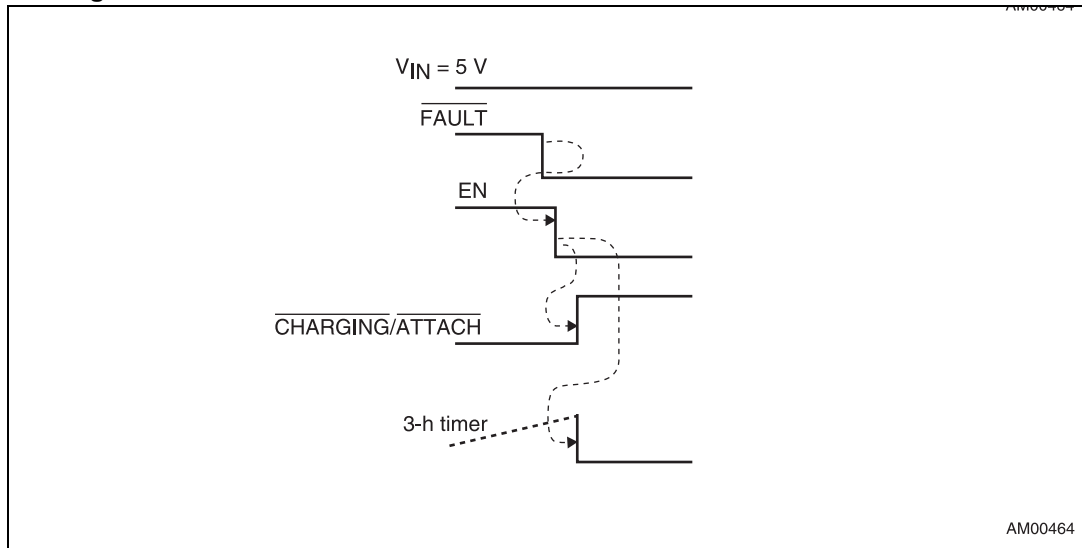

Figure 10. Reset of CHARGING/ATTACH and 3-hour timer after EN -> 0 event

5.7 Power switch

Overcurrent conditions

When an overcurrent condition is detected, the device maintains a constant output current and reduces the voltage accordingly. There are two overload conditions:

- The first one occurs when a short-circuit or a partial short-circuit is already present when the device is being powered up or enabled. The output voltage is held near zero potential with respect to ground and the STCC50x1 device ramps the output current to I_{OS} until the overload condition is removed or the device starts thermal cycle.
- The second condition is when a short-circuit, a partial short-circuit, or a transient overload occurs while the device is already enabled and powered-on. The STCC50x1 device responds to the overcurrent condition within time t_{IOS} . The current sense amplifier is overdriven during this time and momentarily disables the internal current limit MOSFET. It then recovers and ramps the output current to I_{OS} . Similar to the previous condition, it limits output current to I_{OS} until the overload condition is removed or thermal cycle starts.

Thermal protection

The STCC50x1 devices have an internal thermal sensing circuit which monitors the operating temperature of the circuit. It disables power switch operation if die temperature exceeds temperature threshold T_{STOP} , set at 150 °C. The thermal sensor has a hysteresis of 20 °C. The switch turns on if the temperature has cooled down by 20 °C.

Undervoltage lockout

The UVLO circuit disables the circuit until the input voltage reaches the UVLO turn-on threshold. Built-in hysteresis prevents unwanted on/off cycling due to input voltage drop during turn-on.

$\overline{\text{FAULT}}$ functionality

The $\overline{\text{FAULT}}$ open drain active low output is asserted during overcurrent or overtemperature conditions. Signal is asserted until the fault is removed.

For overcurrent conditions, the STCC50x1 device is designed to eliminate false $\overline{\text{FAULT}}$ reporting, by using an internal deglitch delay (9 ms typ.).

In the case of overtemperature, there is no deglitch delay and the $\overline{\text{FAULT}}$ signal is asserted immediately. It is deasserted with delay after the device has cooled down and begins to turn on. This unidirectional glitch immunity prevents $\overline{\text{FAULT}}$ oscillation during an overtemperature event.

In the case of fault condition, the host may disable the power switch by toggling EN input to logic low (see [Figure 10](#)).

Current limit programming

Current limit can be adjusted by an external resistor in the range 500 mA to 2.8 A (typ.). The programming resistor may be calculated using [Equation 1](#) to [Equation 3](#):

Equation 1

$$I_{OS(\text{typ})} = \frac{48000}{R_{ILIM}} (\text{mA}, \text{k}\Omega)$$

Equation 2

$$I_{OS(\text{min})} = \frac{48000}{R_{ILIM}^{1.037}} (\text{mA}, \text{k}\Omega)$$

Equation 3

$$I_{OS(\text{max})} = \frac{48000}{R_{ILIM}^{0.962}} (\text{mA}, \text{k}\Omega)$$

[Equation 2](#) and [Equation 3](#) allow the minimum and maximum variation to be estimated around the typical value predefined by the external resistor, R_{ILIM} , given in [Equation 1](#).

[Equation 2](#) and [Equation 3](#) do not take into consideration external resistor variations.

5.8 EN functionality

The enable input (EN, active high) serves to turn off the STCC50x1 device and achieve the lowest current consumption.

The behavior of the STCC50x1 device in disabled state (EN = 0) is as follows:

- Power switch, USB data switch and emulation profiles are turned off
- The $\overline{\text{FAULT}}$ and $\overline{\text{CHARGING/ATTACH}}$ flags are cleared (the $\overline{\text{FAULT}}$ and $\overline{\text{CHARGING/ATTACH}}$ outputs are set to Hi-Z mode)
- If ATTACH_EN = 0, permanent output discharge is turned on
- If ATTACH_EN = 1, the device turns into the attach detection mode.

5.9 Input and output capacitors

For proper functionality the STCC50x1 device requires 1 μF decoupling ceramic capacitors C_{IN} , C_{VDD} and C_{OUT} (see [Figure 4](#)). These capacitors should be placed as close as possible to the corresponding pins.

The electrolytic capacitor C_{VBUS} (see [Figure 4](#)) is required by the USB specification to suppress the voltage and current transients caused by hot plugging/unplugging the peripheral devices. This capacitor should be placed as close as possible to the USB connector. The recommended value is 150 μF , low ESR type is preferred.

If the V_{IN} supply path is longer than approx. 150 mm, an additional capacitor is required to be connected in parallel to the C_{IN} to suppress V_{IN} overvoltage transients caused by supply path inductance and fast current changes. The minimum value is 10 μF , low ESR type is preferred.

9 Revision history

Table 9. Document revision history

Date	Revision	Changes
20-May-2013	1	Initial release.
24-Jun-2013	2	Updated Features on page 1 (added UL and CB recognized components). Updated note 3. below Table 2 (updated data, added cross-reference to Figure 4). Updated Table 4 (updated parameters and conditions to $I_{REVERSE}$, $I_{OL(FAULT)}$, $I_{OL(CHARGING/ATTACH)}$, I_{CTLX} , $I_{OL(CHARGING/ATTACH)}$ symbols, added I_{ATTACH_EN} symbol). Added Figure 4 on page 12 . Added Note: in Section 5.1 on page 13 . Added Section 5.9 on page 22 .
06-Dec-2013	3	Updated Table 4 (updated min. conditions for $I_{OS} - R_{ILIM}$ 96 k Ω and R_{ILIM} 33 k Ω). Updated Table 5 (updated Host state column, added footnote 1. and 2. below table). Updated Section 5.7 (replaced equation by Equation 1 to Equation 3). Minor modifications throughout document.
06-Feb-2014	4	Replaced adjustable current limit with 2.8 A throughout document Table 4: added current limiter threshold condition " $R_{ILIM} = 17.2$ k Ω "
25-Feb-2014	5	Section 5.7: Power switch: updated Equation 2 and Equation 3 and added explanation of same. Table 8: Order codes: added "Marking"
