

DMOS DUAL FULL BRIDGE DRIVER

- The image displays three different integrated circuit (IC) packages. On the left is a PowerDIP24 package, which is a dual in-line package with 24 pins. In the center is a PowerSO36 package, which is a surface-mount package with 36 pins. On the right is an SO24 package, which is a small outline package with 24 pins. Below each package is its name and pin configuration: PowerDIP24 (20+2+2), PowerSO36, and SO24 (20+2+2). Below these is the heading 'ORDERING NUMBERS:' followed by three examples: L6206N (PowerDIP24), L6206PD (PowerSO36), and L6206D (SO24).

- BIPOLAR STEPPER MOTOR
- DUAL OR QUAD DC MOTOR

The L6206 is a DMOS Dual Full Bridge designed for motor control applications, realized in MultiPower-

BCD technology, which combines isolated DMOS Power Transistors with CMOS and bipolar circuits on the same chip. Available in PowerDIP24 (20+2+2), PowerSO36 and SO24 (20+2+2) packages, the L6206 features thermal shutdown and a non-dissipative overcurrent detection on the high side Power MOSFETs plus a diagnostic output that can be easily used to implement the overcurrent protection.

The diagram illustrates the internal architecture of the D99IN1088A, a dual-channel motor driver. It is divided into two main sections: BRIDGE A and BRIDGE B, each enclosed in a dashed box.

BRIDGE A:
 - **Inputs:** VBOOT, VCP, PROGCL_A, OCD_A, EN_A, IN1_A, IN2_A.
 - **Internal Blocks:** CHARGE PUMP, OVER CURRENT DETECTION, THERMAL PROTECTION, GATE LOGIC, and VOLTAGE REGULATOR (providing 10V and 5V).
 - **Outputs:** VS_A, OUT1_A, OUT2_A, and SENSE_A.
 - **Internal Structure:** The bridge contains four MOSFETs (two N-channel and two P-channel) and four diodes, driven by the GATE LOGIC and powered by the 10V and 5V regulators.
BRIDGE B:
 - **Inputs:** OCD_B, PROGCL_B, EN_B, IN1_B, IN2_B.
 - **Internal Blocks:** OVER CURRENT DETECTION and GATE LOGIC.
 - **Outputs:** VS_B, OUT1_B, OUT2_B, and SENSE_B.
 - **Internal Structure:** Similar to Bridge A, it contains four MOSFETs and four diodes driven by the GATE LOGIC.

ABSOLUTE MAXIMUM RATINGS

Symbol	Parameter	Test conditions	Value	Unit

CIRCUIT DESCRIPTION

POWER STAGES and CHARGE PUMP

The L6206 integrates two independent Power MOS Full Bridges. Each Power MOS has an $R_{ds(on)} = 0.3 \Omega$ (typical value @ 25°C), with intrinsic fast freewheeling diode. Cross conduction protection is achieved using a dead time ($t_d = 1 \mu s$ typical) between the switch off and switch on of two Power MOS in one leg of a bridge.

Using N Channel Power MOS for the upper transistors in the bridge requires a gate drive voltage above the power supply voltage. The Bootstrapped (Vboot) supply is obtained through an internal Oscillator and few external components to realize a charge pump circuit as shown in Figure 3. The oscillator output (VCP) is a square wave at 600kHz (typical) with 10V amplitude. Recommended values/part numbers for the charge pump circuit are shown in Table1.

Table 1. Charge Pump External Components Values

C _{BOOT}	220nF

Figure 3. Charge Pump Circuit

LOGIC INPUTS

Pins IN_{1A}, IN_{2A}, IN_{1B}, IN_{2B}, EN_A and EN_B are TTL/CMOS and uC compatible logic inputs. The internal structure is shown in Fig. 4. Typical value for turn-on and turn-off thresholds are respectively $V_{thon}=1.8V$ and $V_{thoff} = 1.3V$.

Pins EN_A and EN_B are commonly used to implement Overcurrent and Thermal protection by connecting them respectively to the outputs OCD_A and OCD_B, which are open-drain outputs. If that type of connection is chosen, some care needs to be taken in driving

these pins. Two configurations are shown in Fig. 5 and Fig. 6. If driven by an open drain (collector) structure, a pull-up resistor R_{EN} and a capacitor C_{EN} are connected as shown in Fig. 5. If the driver is a standard Push-Pull structure the resistor R_{EN} and the capacitor C_{EN} are connected as shown in Fig. 6. The resistor R_{EN} should be chosen in the range from 2.2k Ω to 180K Ω . Recommended values for R_{EN} and C_{EN} are respectively 100K Ω and 5.6nF. More information on selecting the values is found in the Over-current Protection section.

NON-DISSIPATIVE OVERCURRENT DETECTION AND PROTECTION

In addition to the PWM current control, an overcurrent detection circuit (OCD) is integrated. This circuit can be used to provides protection against a short circuit to ground or between two phases of the bridge as well as a roughly regulation of the load current. With this internal over current detection, the external current sense resistor normally used and its associated power dissipation are eliminated. Fig. 7 shows a simplified schematic of the overcurrent detection circuit for the Bridge A. Bridge B is provided of an analogous circuit.

To implement the over current detection, a sensing element that delivers a small but precise fraction of the output current is implemented with each high side power MOS. Since this current is a small fraction of the output current there is very little additional power dissipation. This current is compared with an internal reference current I_{REF} . When the output current reaches the detection threshold I_{OVER} the OCD comparator signals a fault condition. When a fault condition is detected, an internal open drain MOS with a pull down capability of 4mA connected to OCD pin is turned on. Fig. 8 shows the OCD operation.

This signal can be used to regulate the output current simply by connecting the OCD pin to EN pin and adding an external R-C as shown in Fig.7. The off time before recovering normal operation can be easily programmed by means of the accurate thresholds of the logic inputs.

I_{REF} and, therefore, the output current detection threshold are selectable by R_{CL} value, following the equations:

- $I_{OVER} = 5.6A \pm 30\%$ at $-25^{\circ}C < T_j < 125^{\circ}C$ if $R_{CL} = 0\Omega$ (PROGCL connected to GND)
- $I_{OVER} = \frac{22100}{R_{CL}} \pm 10\%$ at $-25^{\circ}C < T_j < 125^{\circ}C$ if $5K\Omega < R_{CL} < 40k\Omega$

Fig. 9 shows the output current protection threshold versus R_{CL} value in the range 5k Ω to 40k Ω .

The Disable Time $t_{DISABLE}$ before recovering normal operation can be easily programmed by means of the accurate thresholds of the logic inputs. It is affected whether by C_{EN} and R_{EN} values and its magnitude is reported in Figure 10. The Delay Time t_{DELAY} before turning off the bridge when an overcurrent has been detected depends only by C_{EN} value. Its magnitude is reported in Figure 11.

C_{EN} is also used for providing immunity to pin EN against fast transient noises. Therefore the value of C_{EN} should be chosen as big as possible according to the maximum tolerable Delay Time and the R_{EN} value should be chosen according to the desired Disable Time.

The resistor R_{EN} should be chosen in the range from 2.2K Ω to 180K Ω . Recommended values for R_{EN} and C_{EN} are respectively 100K Ω and 5.6nF that allow obtaining 200 μ s Disable Time.

Figure 11. t_{DELAY} versus C_{EN} ($V_{\text{DD}} = 5\text{V}$).

THERMAL PROTECTION

In addition to the Overcurrent Detection, the L6206 integrates a Thermal Protection for preventing the device destruction in case of junction over temperature. It works sensing the die temperature by means of a sensible element integrated in the die. The device switch-off when the junction temperature reaches 165°C (typ. value) with 15°C hysteresis (typ. value).

APPLICATION INFORMATION

A typical application using L6206 is shown in Fig. 12. Typical component values for the application are shown in Table 2. A high quality ceramic capacitor in the range of 100 to 200 nF should be placed between the power pins (VS_A and VS_B) and ground near the L6206 to improve the high frequency filtering on the power supply and reduce high frequency transients generated by the switching. The capacitors connected from the EN_A/OCD_A and EN_B/OCD_B nodes to ground set the shut down time for the Bridge A and Bridge B respectively when an over current is detected (see Overcurrent Protection). The two current sources ($SENSE_A$ and $SENSE_B$) should be connected to Power Ground with a trace length as short as possible in the layout. To increase noise immunity, unused logic pins are best connected to 5V (High Logic Level) or GND (Low Logic Level) (see pin description). It is recommended to keep Power Ground and Signal Ground separated on PCB.

Figure 12. Typical Application

PARALLELED OPERATION

The outputs of the L6206 can be paralleled to increase the output current capability or reduce the power dissipation in the device at a given current level. It must be noted, however, that the internal wire bond connections from the die to the power or sense pins of the package must carry current in both of the associated half bridges. When the two halves of one full bridge (for example OUT1_A and OUT2_A) are connected in parallel, the peak current rating is not increased since the total current must still flow through one bond wire on the power supply or sense pin. In addition the over current detection senses the sum of the current in the upper devices of each bridge (A or B) so connecting the two halves of one bridge in parallel does not increase the over current detection threshold.

For most applications the recommended configuration is Half Bridge 1 of Bridge A paralleled with the Half Bridge 1 of the Bridge B, and the same for the Half Bridges 2 as shown in Figure 13. The current in the two devices connected in parallel will share very well since the $R_{DS(ON)}$ of the devices on the same die is well matched.

When connected in this configuration the over current detection circuit, which senses the current in each bridge (A and B), will sense the current in upper devices connected in parallel independently and the sense circuit with the lowest threshold will trip first. With the enables connected in parallel, the first detection of an over current in either upper DMOS device will turn off both bridges. Assuming that the two DMOS devices share the current equally, the resulting over current detection threshold will be twice the minimum threshold set by the resistors R_{CLA} or R_{CLB} in figure 13. It is recommended to use $R_{CLA} = R_{CLB}$.

In this configuration the resulting Bridge has the following characteristics.

- Equivalent Device: FULL BRIDGE
- $R_{DS(ON)}$ 0.15 Ω Typ. Value @ $T_J = 25^\circ\text{C}$
- 5.6A max RMS Load Current
- 11.2A max OCD Threshold

Figure 13. Parallel connection for higher current

To operate the device in parallel and maintain a lower over current threshold, Half Bridge 1 and the Half Bridge 2 of the Bridge A can be connected in parallel and the same done for the Bridge B as shown in Figure 14. In this configuration, the peak current for each half bridge is still limited by the bond wires for the supply and sense pins so the dissipation in the device will be reduced, but the peak current rating is not increased.

When connected in this configuration the over current detection circuit, senses the sum of the current in upper devices connected in parallel. With the enables connected in parallel, an over current will turn of both bridges. Since the circuit senses the total current in the upper devices, the over current threshold is equal to the threshold set the resistor R_{CLA} or R_{CLB} in figure 14. R_{CLA} sets the threshold when outputs $OUT1_A$ and $OUT2_A$ are high and resistor R_{CLB} sets the threshold when outputs $OUT1_B$ and $OUT2_B$ are high.

It is recommended to use $R_{CLA} = R_{CLB}$.

In this configuration, the resulting bridge has the following characteristics.

- Equivalent Device: FULL BRIDGE
- $R_{DS(ON)}$ 0.15 Ω Typ. Value @ $T_J = 25^\circ\text{C}$
- 2.8A max RMS Load Current
- 5.6A max OCD Threshold

Figure 14. Parallel connection with lower Overcurrent Threshold

It is also possible to parallel the four Half Bridges to obtain a simple Half Bridge as shown in Fig. 15. In this configuration the, the over current threshold is equal to twice the minimum threshold set by the resistors R_{CLA} or R_{CLB} in Figure 15. It is recommended to use $R_{CLA} = R_{CLB}$.

The resulting half bridge has the following characteristics.

- Equivalent Device: HALF BRIDGE
- $R_{DS(ON)}$ 0.075 Ω Typ. Value @ $T_J = 25^\circ\text{C}$
- 5.6A max RMS Load Current
- 11.2A max OCD Threshold

Figure 15. Paralleling the four Half Bridges

OUTPUT CURRENT CAPABILITY AND IC POWER DISSIPATION

In Fig. 16 and Fig. 17 are shown the approximate relation between the output current and the IC power dissipation using PWM current control driving two loads, for two different driving types:

- One Full Bridge ON at a time (Fig.16) in which only one load at a time is energized.
 - Two Full Bridges ON at the same time (Fig.17) in which two loads at the same time are energized.
- For a given output current and driving type the power dissipated by the IC can be easily evaluated, in order to establish which package should be used and how large must be the on-board copper dissipating area to guarantee a safe operating junction temperature (125°C maximum).

Figure 16. IC Power Dissipation versus Output Current with One Full Bridge ON at a time.

Figure 17. IC Power Dissipation versus Output Current with Two Full Bridges ON at the same time.

THERMAL MANAGEMENT

In most applications the power dissipation in the IC is the main factor that sets the maximum current that can be delivered by the device in a safe operating condition. Therefore, it has to be taken into account very carefully. Besides the available space on the PCB, the right package should be chosen considering the power dissipation. Heat sinking can be achieved using copper on the PCB with proper area and thickness. Figures 19, 20 and 21 show the Junction-to-Ambient Thermal Resistance values for the PowerSO36, PowerDIP24 and SO24 packages.

For instance, using a PowerSO package with copper slug soldered on a 1.5 mm copper thickness FR4 board with 6cm² dissipating footprint (copper thickness of 35μm), the $R_{thj-amb}$ is about 35°C/W. Fig. 18 shows mounting methods for this package. Using a multi-layer board with vias to a ground plane, thermal impedance can be reduced down to 15°C/W.
