

# Single Resistor Gain Programmable, Precision Instrumentation Amplifier

## FEATURES

- **Single Gain Set Resistor:**  $G = 1$  to 10,000
- **Gain Error:**  $G = 10$ , 0.08% Max
- **Input Offset Voltage Drift:** 0.3 $\mu$ V/ $^{\circ}$ C Max
- **Meets IEC 1000-4-2 Level 4 ESD Tests with Two External 5k Resistors**
- Gain Nonlinearity:  $G = 10$ , 10ppm Max
- Input Offset Voltage:  $G = 10$ , 60 $\mu$ V Max
- Input Bias Current: 350pA Max
- PSRR at  $G = 1$ : 105dB Min
- CMRR at  $G = 1$ : 90dB Min
- Supply Current: 1.3mA Max
- Wide Supply Range:  $\pm 2.3$ V to  $\pm 18$ V
- 1kHz Voltage Noise: 7.5nV/ $\sqrt{\text{Hz}}$
- 0.1Hz to 10Hz Noise: 0.28 $\mu$ V<sub>P-P</sub>
- Available in 8-Pin PDIP and SO Packages

## APPLICATIONS

- Bridge Amplifiers
- Strain Gauge Amplifiers
- Thermocouple Amplifiers
- Differential to Single-Ended Converters
- Medical Instrumentation

## DESCRIPTION

The LT<sup>®</sup>1167 is a low power, precision instrumentation amplifier that requires only one external resistor to set gains of 1 to 10,000. The low voltage noise of 7.5nV/ $\sqrt{\text{Hz}}$  (at 1kHz) is not compromised by low power dissipation (0.9mA typical for  $\pm 2.3$ V to  $\pm 15$ V supplies).

The part's high accuracy (10ppm maximum nonlinearity, 0.08% max gain error ( $G = 10$ )) is not degraded even for load resistors as low as 2k. The LT1167 is laser trimmed for very low input offset voltage (40 $\mu$ V max), drift (0.3 $\mu$ V/ $^{\circ}$ C), high CMRR (90dB,  $G = 1$ ) and PSRR (105dB,  $G = 1$ ). Low input bias currents of 350pA max are achieved with the use of superbeta processing. The output can handle capacitive loads up to 1000pF in any gain configuration while the inputs are ESD protected up to 13kV (human body). The LT1167 with two external 5k resistors passes the IEC 1000-4-2 level 4 specification.

The LT1167, offered in 8-pin PDIP and SO packages, requires significantly less PC board area than discrete multi op amp and resistor designs.

The LT1167-1 offers the same performance as the LT1167, but its input current characteristic at high common mode voltage better supports applications with high input impedance (see the Applications Information section).

## TYPICAL APPLICATION

Single Supply Barometer

Gain Nonlinearity

## ABSOLUTE MAXIMUM RATINGS

(Note 1)

**Note 1:** Stresses beyond those listed under Absolute Maximum Ratings may cause permanent damage to the device. Exposure to any Absolute Maximum Rating condition for extended periods may affect device reliability and lifetime.

**Note 2:** Does not include the effect of the external gain resistor  $R_G$ .

**Note 3:** This parameter is not 100% tested.

**Note 4:** The LT1167AC/LT1167C/LT1167AC-1/LT1167C-1 are designed, characterized and expected to meet the industrial temperature limits, but are not tested at  $-40^\circ\text{C}$  and  $85^\circ\text{C}$ . I-grade parts are guaranteed.

**Note 5:** This parameter is measured in a high speed automatic tester that does not measure the thermal effects with longer time constants. The magnitude of these thermal effects are dependent on the package used, heat sinking and air flow conditions.

**Note 6:** Hysteresis in offset voltage is created by package stress that differs depending on whether the IC was previously at a higher or lower temperature. Offset voltage hysteresis is always measured at  $25^\circ\text{C}$ , but the IC is cycled to  $85^\circ\text{C}$  I-grade (or  $70^\circ\text{C}$  C-grade) or  $-40^\circ\text{C}$  I-grade ( $0^\circ\text{C}$  C-grade) before successive measurement. 60% of the parts will pass the typical limit on the data sheet.

**Note 7:** Typical parameters are defined as the 60% of the yield parameter distribution.

**Note 8:** Referred to input.

## BLOCK DIAGRAM

Figure 1. Block Diagram

## THEORY OF OPERATION

The LT1167 is a modified version of the three op amp instrumentation amplifier. Laser trimming and monolithic construction allow tight matching and tracking of circuit parameters over the specified temperature range. Refer to the block diagram (Figure 1) to understand the following circuit description. The collector currents in Q1 and Q2 are trimmed to minimize offset voltage drift, thus assuring a high level of performance. R1 and R2 are trimmed to an absolute value of 24.7k to assure that the gain can be set accurately (0.05% at  $G = 100$ ) with only one external resistor  $R_G$ . The value of  $R_G$  determines the transconductance of the preamp stage. As  $R_G$  is reduced for larger programmed gains, the transconductance of the input preamp stage increases to that of the input transistors Q1 and Q2. This increases the open-loop gain when the programmed gain is increased, reducing the input referred gain related errors and noise. The input voltage noise at gains greater than 50 is determined only by Q1 and Q2. At lower gains the noise of the difference amplifier and preamp gain setting resistors increase the noise. The gain bandwidth product is determined by C1, C2 and the preamp transconductance which increases

with programmed gain. Therefore, the bandwidth does not drop proportionally to gain.

The input transistors Q1 and Q2 offer excellent matching, which is inherent in NPN bipolar transistors, as well as picoampere input bias current due to superbeta processing. The collector currents in Q1 and Q2 are held constant due to the feedback through the Q1-A1-R1 loop and Q2-A2-R2 loop which in turn impresses the differential input voltage across the external gain set resistor  $R_G$ . Since the current that flows through  $R_G$  also flows through R1 and R2, the ratios provide a gained-up differential voltage,  $G = (R1 + R2)/R_G$ , to the unity-gain difference amplifier A3. The common mode voltage is removed by A3, resulting in a single-ended output voltage referenced to the voltage on the REF pin. The resulting gain equation is:

$$V_{OUT} - V_{REF} = G(V_{IN}^{+} - V_{IN}^{-})$$

where:

$$G = (49.4k\Omega/R_G) + 1$$

solving for the gain set resistor gives:

$$R_G = 49.4k\Omega/(G - 1)$$

## THEORY OF OPERATION

Figure 3. Providing an Input Common Mode Current Path

## APPLICATIONS INFORMATION

The LT1167 is a low power precision instrumentation amplifier that requires only one external resistor to accurately set the gain anywhere from 1 to 1000. The output can handle capacitive loads up to 1000pF in any gain configuration and the inputs are protected against ESD strikes up to 13kV (human body).

### Input Current at High Common Mode Voltage

When operating within the specified input common mode range, both the LT1167 and LT1167-1 operate as shown in the Input Bias Current vs Common Mode Input Voltage graph shown in the Typical Performance Characteristics. If however the inputs are within approximately 0.8V of the positive supply, the LT1167 input current will increase to approximately  $-1\mu\text{A}$  to  $-3\mu\text{A}$ . If the impedance of the circuit driving the LT1167 inputs is sufficiently high (e.g.,  $10\text{M}\Omega$  when  $+V_S = 15\text{V}$ ), this increased input current can pull the input voltage sufficiently high to keep the elevated input current flowing. The LT1167-1 has been modified so that the input current is typically two orders of magnitude lower under similar conditions. The LT1167-1 is recommended for new designs where input impedance is high.

### Input Protection

The LT1167 can safely handle up to  $\pm 20\text{mA}$  of input current in an overload condition. Adding an external 5k input resistor in series with each input allows DC input fault voltages up to  $\pm 100\text{V}$  and improves the ESD immunity to 8kV (contact) and 15kV (air discharge), which is the IEC 1000-4-2 level 4 specification. If lower value input

resistors are needed, a clamp diode from the positive supply to each input will maintain the IEC 1000-4-2 specification to level 4 for both air and contact discharge. A 2N4393 drain/source to gate is a good low leakage diode for use with 1k resistors, see Figure 4. The input resistors should be carbon and not metal film or carbon film.

Figure 4. Input Protection

### RFI Reduction

In many industrial and data acquisition applications, instrumentation amplifiers are used to accurately amplify small signals in the presence of large common mode voltages or high levels of noise. Typically, the sources of these very small signals (on the order of microvolts or millivolts) are sensors that can be a significant distance from the signal conditioning circuit. Although these sensors may be connected to signal conditioning circuitry, using shielded or unshielded twisted-pair cabling, the cabling may act as antennae, conveying very high frequency interference directly into the input stage of the LT1167.

## APPLICATIONS INFORMATION

The amplitude and frequency of the interference can have an adverse effect on an instrumentation amplifier's input stage by causing an unwanted DC shift in the amplifier's input offset voltage. This well known effect is called RFI rectification and is produced when out-of-band interference is coupled (inductively, capacitively or via radiation) and rectified by the instrumentation amplifier's input transistors. These transistors act as high frequency signal detectors, in the same way diodes were used as RF envelope detectors in early radio designs. Regardless of the type of interference or the method by which it is coupled into the circuit, an out-of-band error signal appears in series with the instrumentation amplifier's inputs.

To significantly reduce the effect of these out-of-band signals on the input offset voltage of instrumentation amplifiers, simple lowpass filters can be used at the inputs. These filters should be located very close to the input pins of the circuit. An effective filter configuration is illustrated in Figure 5, where three capacitors have been added to the inputs of the LT1167. Capacitors  $C_{XCM1}$  and  $C_{XCM2}$  form lowpass filters with the external series resistors  $R_{S1,2}$  to any out-of-band signal appearing on each of the input traces. Capacitor  $C_{XD}$  forms a filter to reduce any unwanted signal that would appear across the input traces. An added benefit to using  $C_{XD}$  is that the circuit's AC common mode rejection is not degraded due to common mode capacitive

imbalance. The differential mode and common mode time constants associated with the capacitors are:

$$t_{DM(LPF)} = (2)(R_S)(C_{XD})$$

$$t_{CM(LPF)} = (R_{S1,2})(C_{XCM1,2})$$

Setting the time constants requires a knowledge of the frequency, or frequencies of the interference. Once this frequency is known, the common mode time constants can be set followed by the differential mode time constant. To avoid any possibility of inadvertently affecting the signal to be processed, set the common mode time constant an order of magnitude (or more) larger than the differential mode time constant. Set the common mode time constants such that they do not degrade the LT1167's inherent AC CMR. Then the differential mode time constant can be set for the bandwidth required for the application. Setting the differential mode time constant close to the sensor's BW also minimizes any noise pickup along the leads. To avoid any possibility of common mode to differential mode signal conversion, match the common mode time constants to 1% or better. If the sensor is an RTD or a resistive strain gauge, then the series resistors  $R_{S1,2}$  can be omitted, if the sensor is in proximity to the instrumentation amplifier.

### “Roll Your Own”—Discrete vs Monolithic LT1167 Error Budget Analysis

The LT1167 offers performance superior to that of “roll your own” three op amp discrete designs. A typical application that amplifies and buffers a bridge transducer's differential output is shown in Figure 6. The amplifier, with its gain set to 100, amplifies a differential, full-scale output voltage of 20mV over the industrial temperature range. To make the comparison challenging, the low cost version of the LT1167 will be compared to a discrete instrumentation amp made with the A grade of one of the best precision quad op amps, the LT1114A. The LT1167C outperforms the discrete amplifier that has lower  $V_{OS}$ , lower  $I_B$  and comparable  $V_{OS}$  drift. The error budget comparison in Table 1 shows how various errors are calculated and how each error affects the total error budget. The table shows the greatest differences between the discrete solution and

$$G = 100, V_S = \pm 15V$$

All errors are min/max and referred to input.

the LT1167 are input offset voltage and CMRR. Note that for the discrete solution, the noise voltage specification is multiplied by  $\sqrt{2}$  which is the RMS sum of the uncorelated noise of the two input amplifiers. Each of the amplifier errors is referenced to a full-scale bridge differential voltage of 20mV. The common mode range of the bridge is 5V. The LT1114 data sheet provides offset voltage, offset voltage drift and offset current specifications for the matched op amp pairs used in the error-budget table. Even with an excellent matched op amp like the LT1114, the discrete solution's total error is significantly higher than the LT1167's

total error. The LT1167 has additional advantages over the discrete design, including lower component cost and smaller size.

## Current Source

Figure 7 shows a simple, accurate, low power programmable current source. The differential voltage across Pins 2 and 3 is mirrored across  $R_G$ . The voltage across  $R_G$  is amplified and applied across  $R_X$ , defining the output current. The 50 $\mu$ A bias current flowing from Pin 5 is buffered by the LT1464 JFET operational amplifier. This

## APPLICATIONS INFORMATION

Figure 7. Precision Voltage-to-Current Converter

has the effect of improving the resolution of the current source to 3pA, which is the maximum  $I_B$  of the LT1464A. Replacing  $R_G$  with a programmable resistor greatly increases the range of available output currents.

### Nerve Impulse Amplifier

The LT1167's low current noise makes it ideal for high source impedance EMG monitors. Demonstrating the LT1167's ability to amplify low level signals, the circuit in Figure 8 takes advantage of the amplifier's high gain and low noise operation. This circuit amplifies the low level nerve impulse signals received from a patient at Pins 2 and 3.  $R_G$  and the parallel combination of  $R_3$  and  $R_4$  set a gain of ten. The potential on LT1112's Pin 1 creates a ground for the common mode signal.  $C_1$  was chosen to maintain the stability of the patient ground. The LT1167's

high CMRR ensures that the desired differential signal is amplified and unwanted common mode signals are attenuated. Since the DC portion of the signal is not important,  $R_6$  and  $C_2$  make up a 0.3Hz highpass filter. The AC signal at LT1112's Pin 5 is amplified by a gain of 101 set by  $(R_7/R_8) + 1$ . The parallel combination of  $C_3$  and  $R_7$  form a lowpass filter that decreases this gain at frequencies above 1kHz. The ability to operate at  $\pm 3V$  on 0.9mA of supply current makes the LT1167 ideal for battery-powered applications. Total supply current for this application is 1.7mA. Proper safeguards, such as isolation, must be added to this circuit to protect the patient from possible harm.

### Low $I_B$ Favors High Impedance Bridges, Lowers Dissipation

The LT1167's low supply current, low supply voltage operation and low input bias currents optimize it for battery-powered applications. Low overall power dissipation necessitates using higher impedance bridges. The single supply pressure monitor application (Figure 9) shows the LT1167 connected to the differential output of a 3.5k bridge. The bridge's impedance is almost an order of magnitude higher than that of the bridge used in the error-budget table. The picoampere input bias currents keep the error caused by offset current to a negligible level. The LT1112 level shifts the LT1167's reference pin and the ADC's analog ground pins above ground. The LT1167's and LT1112's combined power dissipation is still less than the bridge's. This circuit's total supply current is just 2.8mA.

| LT1460      | Precision Series Reference                                        | Micropower; 2.5V, 5V, 10V Versions; High Precision                                               |
| LT1468      | 16-Bit Accurate Op Amp, Low Noise Fast Settling                   | 16-Bit Accuracy at Low and High Frequencies, 90MHz GBW, 22V/ $\mu s$ , 900ns Settling            |
| LTC1562     | Active RC Filter                                                  | Lowpass, Bandpass, Highpass Responses; Low Noise, Low Distortion, Four 2nd Order Filter Sections |
| LTC1605     | 16-Bit, 100ksps, Sampling ADC                                     | Single 5V Supply, Bipolar Input Range: $\pm 10V$ , Power Dissipation: 55mW Typ                   |
